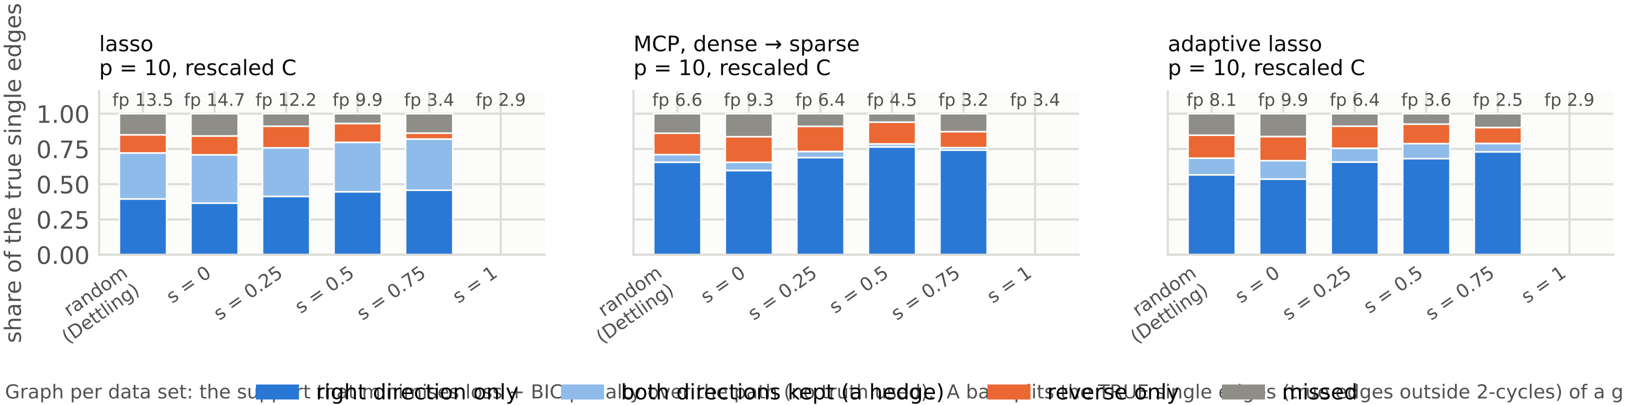
E5: the share of 2-cycles as a knob, direct loss -- the true single edges in the selected graph (BIC), $n = 10^4$ (fp: false positives per graph)
[laptop rehearsal: $p = 10$, true $C = 2I$, 4 replicates, 16 graphs per cell]



Graph per data set: the support that minimises loss + BIC penalty over the path (no truth used). A bar splits the TRUE single edges (true edges outside 2-cycles) of a graph by their fate and always sums to one; it is the mean over the cell's graphs of those shares. The estimated graph's size is not shown: fp = its false positives per graph (hedges + reversals + edges between unconnected nodes).
